Experiment No 2:

Aim: To implement functions and object oriented concepts in python. **Theory:**

Python allows us to divide a large program into the basic building blocks known as a function. The function contains the set of programming statements enclosed in a block. A function can be called multiple times to provide reusability and modularity to the Python program.

Creating a Function

Python provides the **def** keyword to define the function. The syntax of the define function is given below.

Syntax:

1. **def** my_function(parameters):
2. function_block
3. **return** expression

Function Calling

In Python, after the function is created, we can call it from another function. A function must be defined before the function call; otherwise, the Python interpreter gives an error. To call the function, use the function name followed by the parentheses.

Recursive function

A function that calls itself is a recursive function. This method is used when a certain problem is defined in terms of itself. Although this involves iteration, using an iterative approach to solve such a problem can be tedious.

Classes and Objects

Classes are used to create user-defined data structures. Classes define functions called **methods**, which identify the behaviors and actions that an object created from the class can perform with its data.

While the class is the blueprint, an **instance** is an object that is built from a class and contains real data

Vidyavardhini's College of Engineering and Technology

Department of Artificial Intelligence & Data Science

Class Definition Syntax:

```
class ClassName:
```

```
# Statement-1
```

```
.
```

```
.
```

```
.
```

```
# Statement-N
```

Instantiate an Object in Python

```
Instance_name=ClassName()
```

Instance attributes and class attributes

Attributes created in `.__init__()` are called **instance attributes**. An instance attribute's value is specific to a particular instance of the class.

On the other hand, **class attributes** are attributes that have the same value for all class instances. You can define a class attribute by assigning a value to a variable name outside of `.__init__()`.

The self

Class methods must have an extra first parameter in the method definition. We do not give a value for this parameter when we call the method, Python provides it. If we have a method that takes no arguments, then we still have to have one argument.

`__init__` method

The `__init__` method is similar to constructors in C++ and Java. Constructors are used to initializing the object's state.

Inheritance in Python:

Vidyavardhini's College of Engineering and Technology

Department of Artificial Intelligence & Data Science

Inheritance is the capability of a class to inherit all properties and methods of base class from which it is derived and can add new features to the class without modifying it. The syntax to define a derived class when one or more base classes are to be inherited is as follows:

class derivedClassName(baseClassName,...):

<statement
1>.

<statement
n>

Different forms of Inheritance:

1. Single inheritance:

When a child class inherits from only one parent class, it is called single inheritance. We saw an example above.

2. Multiple inheritance:

When a child class inherits from multiple parent classes, it is called multiple inheritance. Unlike java, python shows multiple inheritance.

3. Multilevel inheritance:

When we have a child and grandchild relationship.

4. Hierarchical inheritance

More than one derived classes are created from a single base.

Vidyavardhini's College of Engineering and Technology

Department of Artificial Intelligence & Data Science

5. Hybrid inheritance:

This form combines more than one form of inheritance. Basically, it is a blend of more than

one type of inheritance.

PROGRAM:

```
# This is simplest Student data management program in python
```

```
# Create class "Student"
```

```
class Student:
```

```
# Constructor
```

```
def __init__(self, name, rollno, m1, m2):
```

```
    self.name = name
```

```
    self.rollno = rollno
```

```
    self.m1 = m1
```

```
    self.m2 = m2
```

```
#ob = Student(name, rollno, m1, m2 )this will give error
```

```
# Function to create and append new student
```

```
def accept(self, Name, Rollno, marks1, marks2 ):
```

```
# use ' int(input()) ' method to take input from user
```

```
ob = Student(Name, Rollno, marks1, marks2 )
```

```
ls.append(ob)
```

```
# Function to display student details
```

```
def display(self, ob):
```

```
    print("Name : ", ob.name)
```

Vidyavardhini's College of Engineering and Technology

Department of Artificial Intelligence & Data Science

```
print("RollNo : ", ob.rollno)
```

```
print("Marks1 : ", ob.m1)
```

```
print("Marks2 : ", ob.m2)
```

```
print("\n")
```

```
# Search Function
```

```
def search(self, rn):
```

```
for i in range(ls.__len__()):
```

```
if(ls[i].rollno == rn):
```

```
return i
```

```
# Delete Function
```

```
def delete(self, rn):
```

```
i = obj.search(rn)
```

```
del ls[i]
```

```
# Update Function
```

```
def update(self, rn, No):
```

```
i = obj.search(rn)
```

```
roll = No
```

```
ls[i].rollno = roll;
```

Department of Artificial Intelligence & Data Science

```
# Create a list to add Students
```

```
ls = []
```

```
# an object of Student class
```

```
obj = Student("", 0, 0, 0)
```

```
print("\nOperations used, ")
```

```
print("\n1.Accept Student details\n2.Display Student  
Details\n" "3.Search Details of a Student\n4.Delete  
Details of Student" "5.Update Student  
Details\n6.Exit")
```

```
# ch = int(input("Enter choice:"))
```

```
# if(ch == 1):
```

```
obj.accept("A", 1, 100, 100)
```

```
obj.accept("B", 2, 90, 90)
```

```
obj.accept("C", 3, 80, 80)
```

```
# elif(ch == 2):
```

```
print("\n")
```

```
print("\nList of Students\n")
```

```
for i in range(ls.__len__()):
```

```
obj.display(ls[i])
```

```
# elif(ch == 3):
```

Vidyavardhini's College of Engineering and Technology

Department of Artificial Intelligence & Data Science

```
print("\n Student Found, ")
```

```
s = obj.search(2)
```

```
obj.display(ls[s])
```

```
# elif(ch == 4):
```

```
obj.delete(2)
```

```
print(ls.__len__())
```

```
print("List after deletion")
```

```
for i in range(ls.__len__()):
```

```
    obj.display(ls[i])
```

```
# elif(ch == 5):
```

```
obj.update(3, 2)
```

```
print(ls.__len__())
```

```
print("List after updation")
```

```
for i in range(ls.__len__()):
```

```
    obj.display(ls[i])
```

```
# else:
```

```
print("Thank You !")
```

Conclusion: the implementation of functions and object-oriented concepts in Python

Vidyavardhini's College of Engineering and Technology

Department of Artificial Intelligence & Data Science

proved to be essential in enhancing code modularity, reusability, and maintainability. By effectively utilizing these programming paradigms, we were able to achieve greater flexibility and scalability in our software design, laying a solid foundation for future development endeavors.
